Acknowledgments

This work was partially supported by research subaward 08008-002-011-000 from the Universities Space Research Association and NASA, NASA/University Affiliated Research Center grant SC 2003028 NAS2-03144, Sandia National Laboratories grant 496420, and National Science Foundation grants DMS 0233710 and 0504851. I would like to thank Matt Taddy for his contributions to recent releases of the package. I am especially grateful to my thesis advisor, Herbie Lee, whose contributions and guidance in this project have been invaluable throughout. Finally, I would like to thank an anonymous referee whose many helpful comments improved the paper.

A Implementation notes

The treed GP model is coded in a mixture of `C` and `C++`: `C++` for the tree data structure ($\mathcal{T}$) and `C` for the GP at each leaf of $\mathcal{T}$. The code has been tested on Unix (`Solaris, Linux, FreeBSD, OSX`) and Windows (2000, XP) platforms.

It is useful to first translate and re-scale the input data ($\mathbf{X}$) so that it lies in an $\Re^{m_X}$ dimensional unit cube. This makes it easier to construct prior distributions for the width parameters to the correlation function $K(\cdot,\cdot)$. Proposals for all parameters which require MH sampling are taken from a uniform "sliding window" centered around the location of the last accepted setting. For example, a proposed a new nugget parameter g_ν to the correlation function $K(\cdot,\cdot)$ in region r_ν would go as

$$g_\nu^* \sim \text{Unif}\left(\frac{3}{4}g_\nu, \frac{4}{3}g_\nu\right).$$

Calculating the corresponding forward and backwards proposal probabilities for the MH acceptance ratio is straightforward.

For more details about the MCMC algorithm and proposals, etc., please see the original technical report on *Bayesian treed Gaussian process models* [15].

B Interfaces and features

The following subsections describe some of the ancillary features of the `tgp` package such as the gathering and summarizing of MCMC parameter traces, the progress meter, and an example of how to use the `predict.tgp` function in a collaborative setting.

B.1 Parameter traces

Traces of (almost) all parameters to the `tgp` model can be collected by supplying `trace=TRUE` to the `b*` functions. In the current version, traces for the linear prior correlation matrix ($\mathbf{W}$) are not provided. I shall illustrate the gathering and analyzing of traces through example. But first, a few notes and cautions.

Models which involve treed partitioning may have more than one base model (GP or LM). The process governing a particular input `x` depends on the coordinates of `x`. As such, `tgp` records region–specific traces of parameters to GP (and linear) models at the locations enumerated in the `XX` argument. Even traces of single–parameter Markov chains can require hefty amounts of storage, so recording traces at each of the `XX` locations can be an enormous memory hog. A related warning will be given if the product of |`XX`|, `(BTE[2]-BTE[1])/BTE[3]` and `R` is beyond a threshold. The easiest way to keep the storage requirements for traces down is to control the size of `XX` and the thinning level `BTE[3]`. Finally, traces for most of the parameters are stored in output files. The contents of the trace files are read into `R` and stored as `data.frame` objects, and the files are removed. The existence of partially written trace files in the current working directory (CWD)—while the `C` code is executing—means that not more than one `tgp` run (with `trace = TRUE`) should be active in the CWD at one time.

Consider again the exponential data. For illustrative purposes I chose `XX` locations (where traces are gathered) to be (1) in the interior of the interesting region, (2) on/near the plausible intersection of partition boundaries, and (3) in the interior of the flat region. The hierarchical prior `bprior = "b0"` is used to leverage a (prior) belief the most of the input domain is uninteresting.

```
> exp2d.data <- exp2d.rand(n2 = 150, lh = 0, dopt = 10)
> X <- exp2d.data$X
> Z <- exp2d.data$Z
> XX <- rbind(c(0, 0), c(2, 2), c(4, 4))
```

We now fit a treed GP LLM and gather traces, and also gather EI and ALC statistics for the purposes of illustration. Prediction at the input locations `X` is turned off to be thrifty.

```
> out <- btgpllm(X = X, Z = Z, XX = XX, corr = "exp",
+     bprior = "b0", pred.n = FALSE, Ds2x = TRUE, R = 10,
+     trace = TRUE, verb = 0)
```

Figure 19 shows a dump of `out$trace` which is a `"tgptraces"`–class object. It depicts the full set of parameter traces broken down into the elements of a `list`: `$XX` with GP/LLM parameter traces for each `XX` location (the parameters are listed); `$hier` with traces for (non–input–dependent) hierarchical parameters (listed); `$linarea` recording proportions of the input space under the LLM; `$parts` with the boundaries of all partitions visited; `$post` containing (log) posterior probabilities; `preds` containing traces of samples from the posterior predictive distribution and adaptive sampling statistics.

Plots of traces are useful for assessing the mixing of the Markov chain. For example, Figure 20 plots traces of the range parameter (d) for each of the 3 predictive locations `XX`. It is easy to see which of the locations is in the same partition with others, and which have smaller range parameters than others.

The mean area under the LLM can be calculated as

```
> linarea <- mean(out$trace$linarea$la)
> linarea
```

```
> out$trace

This 'tgptraces'-class object contains traces of the parameters
to a tgp model. Access is as a list:

1.) $XX contains the traces of GP parameters for 3 predictive
    locations

    Each of $XX[[1]] ... $XX[[3]]  is a data frame with the
    columns representing GP parameters:

 [1] index  lambda s2     tau2   beta0  beta1  beta2  nug
 [9] d      b      ldetK

2.) $hier has a trace of the hierarchical params:

 [1] s2.a0   s2.g0   tau2.a0 tau2.g0 beta0   beta1   beta2
 [8] d.a0    d.g0    d.a1    d.g1    nug.a0  nug.g0  nug.a1
[15] nug.g1

3.) $linarea has a trace of areas under the LLM.  It is a
    data frame with columns:

    count: number of booleans b=0, indicating LLM
       la: area of domain under LLM
       ba: area of domain under LLM weighed by dim

4.) $parts contains all of the partitions visited.  Use the
    tgp.plot.parts.[1d,2d] functions for visuals

5.) $post is a data frame with columns showing the following:
    log posterior ($lpost), tree height ($height), IS
    weights ($w), tempered log posterior ($tlpost), inv-temp
    ($itemp), and weights adjusted for ESS ($wess)

6.) $preds is a list containing data.frames for samples from
    the posterior predictive distributions data (X) locations
    (if pred.n=TRUE: $Zp, $Zp.km, $Zp.ks2) and (XX) locations
    (if XX != NULL: $ZZ, $ZZ.km, $ZZ.ks2), with $Ds2x when
    input argument ds2x=TRUE, and $improv when improv=TRUE
```

Figure 19: Listing the contents of "tgptraces"–class objects.

```
> trXX <- out$trace$XX
> ltrXX <- length(trXX)
> y <- trXX[[1]]$d
> for (i in 2:ltrXX) y <- c(y, trXX[[i]]$d)
> plot(log(trXX[[1]]$d), type = "l", ylim = range(log(y)),
+     ylab = "log(d)", main = "range (d) parameter traces")
> names <- "XX[1,]"
> for (i in 2:ltrXX) {
+     lines(log(trXX[[i]]$d), col = i, lty = i)
+     names <- c(names, paste("XX[", i, ",]", sep = ""))
+ }
> legend("bottomleft", names, col = 1:ltrXX, lty = 1:ltrXX)
```

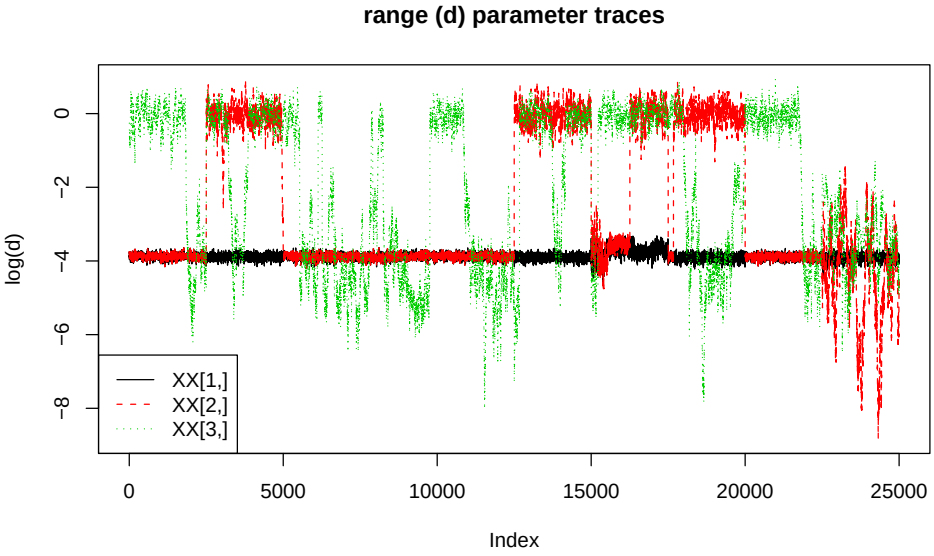

Figure 20: Traces of the (log of the) first range parameter for each of the three `XX` locations

```
[1] 0.530641
```

This means that the expected proportion of the input domain under the full LLM is 0.531. Figure 21 shows a histogram of areas under the LLM. The clumps near 0, 0.25, 0.5, and 0.75 can be thought of as representing quadrants (none, one, two, and tree) under the LLM. Similarly, we can calculate the probability that each of the `XX` locations is governed by the LLM.

```
> m <- matrix(0, nrow = length(trXX), ncol = 3)
> for (i in 1:length(trXX)) m[i, ] <- as.double(c(out$XX[i,
+     ], mean(trXX[[i]]$b)))
> m <- data.frame(cbind(m, 1 - m[, 3]))
> names(m) = c("XX1", "XX2", "b", "pllm")
> m
```

```
> hist(out$trace$linarea$la)
```

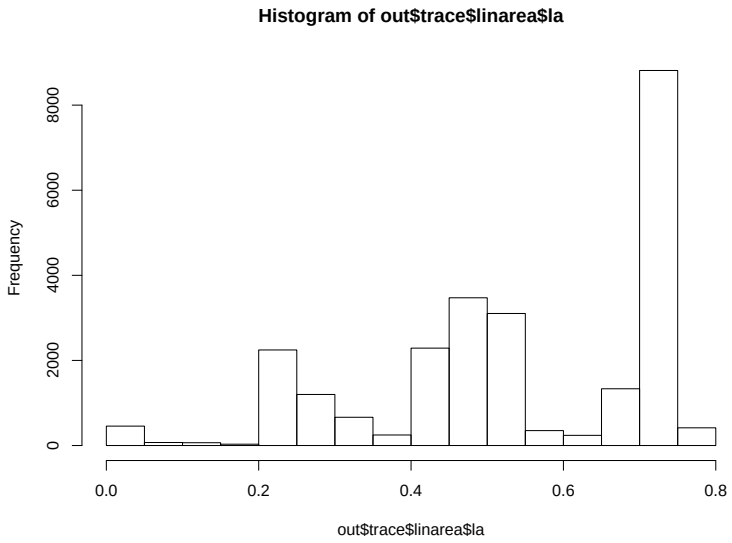

Figure 21: Histogram of proportions of the area of the input domain under the LLM

```
  XX1 XX2       b    pllm
1   0   0 1.00000 0.00000
2   2   2 0.64852 0.35148
3   4   4 0.50384 0.49616
```

The final column above represents the probability that the corresponding `XX` location is under the LLM (which is equal to `1-b`).

Traces of posterior predictive and adaptive sampling statistics are contained in the `$preds` field. For example, Figure 22 shows samples of the ALC statistic $\Delta\sigma^2(\tilde{\mathbf{x}})$. We can see from the trace that statistic is generally lowest for `XX[3,]` which is in the uninteresting region, and that there is some competition between `XX[2,]` which lies on the boundary between the regions, and `XX[1,]` which is in the interior of the interesting region. Similar plots can be made for the other adaptive sampling statistics (i.e., ALM & EI).

B.2 Explaining the progress meter

The progress meter shows the state of the MCMC as it iterates through the desired number of rounds of burn–in (`BTE[1]`), and sampling (`BTE[2]-BTE[1]`), for the requested number of repeats (`R-1`). The verbosity of progress meter print statements is controlled by the `verb` arguments to the `b*` functions. Providing `verb=0` silences all non–warning (or error) statements. To suppress warnings, try enclosing commands within `suppressWarnings(...)`, or globally set `options(warn=0)`. See the help file (`?options`) for more global warning settings.

```
> trALC <- out$trace$preds$Ds2x
> y <- trALC[, 1]
> for (i in 2:ncol(trALC)) y <- c(y, trALC[, i])
> plot(log(trALC[, 1]), type = "l", ylim = range(log(y)),
+     ylab = "Ds2x", main = "ALC: samples from Ds2x")
> names <- "XX[1,]"
> for (i in 2:ncol(trALC)) {
+     lines(log(trALC[, i]), col = i, lty = i)
+     names <- c(names, paste("XX[", i, ",]", sep = ""))
+ }
> legend("bottomright", names, col = 1:ltrXX, lty = 1:ltrXX)
```

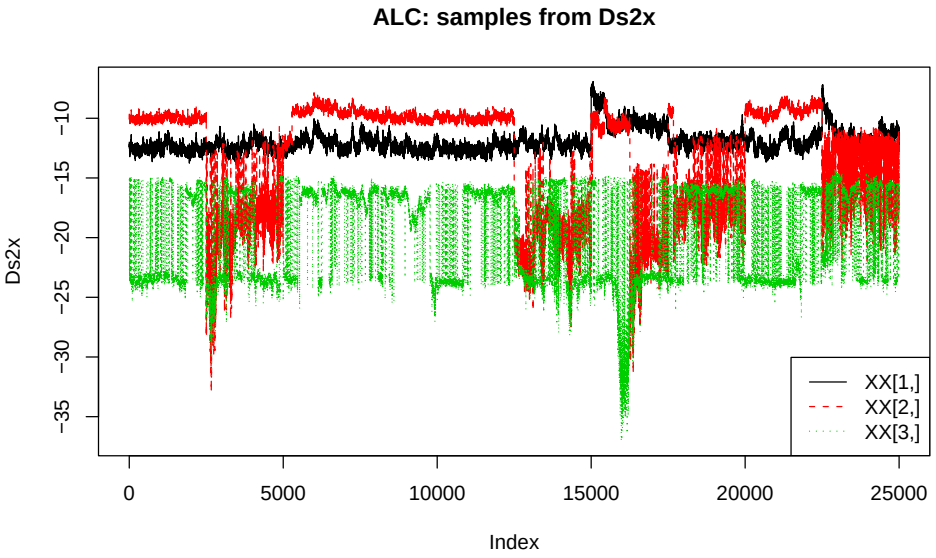

Figure 22: Traces of the (log of the) samples for the ALC statistic $\Delta\sigma^2(\tilde{\mathbf{x}})$ at for each of the three `XX` locations

The default verbosity setting (`verb=1`) shows all *grows* and *prunes*, and a summary of d–(range) parameters for each partition every 1000 rounds. Higher verbosity arguments will show more tree operations, e.g., *change* and *swap*, etc. Setting `verb=2` will cause an echo of the `tgp` model parameters and their starting values; but is otherwise the same as `verb=1`. The max is `verb=4` shows all successful tree operations. Here is an example *grow* statement.

```
**GROW** @depth 2: [0,0.05], n=(10,29)
```

The `*GROW*` statements indicate the depth of the split leaf node; the splitting dimension u and location v is shown between square brackets `[u,v]`, followed by the size of the two new children `n=(n1,n2)`. `*PRUNE*` is about the same, without printing `n=(n1,n2)`.

Every 1000 rounds a progress indicator is printed. Its format depends on a number of things: (1) whether parallelization is turned on or not, (2) the correlation model [isotropic or separable], (3) whether jumps to the LLM are allowed. Here is an example with the 2-d exp data with parallel prediction under the separable correlation function:

```
(r,l)=(5000,104) d=[0.0144 0.0236] [1.047 0/0.626]; mh=2 n=(59,21)
```

The first part `(r,l)=(5000,104)` is indicating the MCMC round number r=5000 and the number of leaves waiting to be "consumed" for prediction by the parallel prediction thread. When parallelization is turned off (default), the print will simply be `"r=5000"`.

The second part is a printing of the d–(range) parameter to a separable correlation function. For 2 partitions there are two sets of square brackets. Inside the square brackets is the m_X (2 in this case) range parameters for the separable correlation function. Whenever the LLM governs one of the input dimensions a zero will appear. I.e., the placement of `0/0.626` indicates the LLM is active in the 2nd dimension of the 2nd partition. 0.626 is the d–(range) parameter that would have been used if the LLM were inactive. Whenever all dimensions are under the LLM, the d-parameter print is simply `[0]`. This also happens when forcing the LLM (i.e., for `blm` and `btlm`), where `[0]` appears for each partition. These prints will look slightly different if the isotropic instead of separable correlation is used, since there are not as many range parameters.

B.3 Collaboration with `predict.tgp`

In this section I revisit the motorcycle accident data in order to demonstrate how the `predict.tgp` function can be helpful in collaborative uses of `tgp`. Consider a fit of the motorcycle data, and suppose that infer the model parameters only (obtaining no samples from the posterior predictive distribution). The `"tgp"`-class output object can be saved to a file using the `R`–internal `save` function.

```
> library(MASS)
> out <- btgpllm(X = mcycle[, 1], Z = mcycle[, 2],
+     bprior = "b0", m0r1 = TRUE, pred.n = FALSE, verb = 0)
> save(out, file = "out.Rsave")
> out <- NULL
```

Note that there is nothing to plot here because there is no predictive data. (`out <- NULL` is set for illustrative purposes.)

Now imagine e–mailing the "out.Rsave" file to a collaborator who wishes to use your fitted `tgp` model. S/he could first load in the `"tgp"`–class object we just saved, design a new set of predictive locations `XX` and obtain kriging estimates from the MAP model.

```
> load("out.Rsave")
> XX <- seq(2.4, 56.7, length = 200)
> out.kp <- predict(out, XX = XX, pred.n = FALSE)
```
